

scientists of the atomic model

John Dalton proposed that all matter is composed of very small things which he called atoms. This was not a completely new concept as the ancient Greeks (notably Democritus) had proposed that all matter is composed of small, indivisible (cannot be divided) objects.

Rutherford new model described the atom as a tiny, dense, positively charged core called a nucleus surrounded by lighter, negatively charged electrons.

J.J. Thomson In this model, the atom is made up of negative electrons that float in a "soup" of positive charge.

James Chadwick discovered the neutron and measured its mass.

Niels Bohr proposed that the electrons could only orbit the nucleus in certain special orbits at different energy levels around the nucleus.
